## 4-ARYLOXINDOLES AS INHIBITORS OF JNK PROTEIN KINASES

5

Protein kinases are a class of proteins that regulate a variety of cellular functions. This is accomplished by the phosphorylation of specific amino acids on protein substrates resulting in conformational alteration of the substrate protein. The  
10 conformational change modulates the activity of the substrate or its ability to interact with other binding partners. The enzyme activity of the protein kinase refers to the rate at which the kinase adds phosphate groups to a substrate. It can be measured, for example, by determining the amount of a substrate that is converted to a product as a function of time. Phosphorylation of a substrate occurs at the active-site of a  
15 protein kinase.

The JNK (Jun N-terminal kinase) protein kinases (also know as "stress-activated protein kinases" or "SAPK") are members of the mitogen-activated protein (MAP) kinases. See, e.g., S. Gupta et al., EMBO J., vol. 15 no. 11 (1996) pp. 2760-  
20 2770; and Yang et al., Nature, vol. 389 (23 October 1997) pp. 865-870. At least ten JNK isoforms are currently known. See, Gupta, *id.* As its name indicates, one of the substrates for JNK is c-Jun. JNK phosphorylates the NH<sub>2</sub>-terminal activation domain of c-Jun on Ser63 and Ser73, causing increased c-Jun transcriptional activity. See Gupta, *id.* In turn, c-Jun is an AP-1 transcription factor that mediates immediate-early  
25 gene expression. See, e.g., A. Minden et al., Biochimica et Biophysica Acta 1333 (1997) F85-F104; and A. Karin, Biochimica et Biophysica Acta, vol.172 (1991) pp.129-157.

The JNK protein kinase is markedly activated in response to treatment of cells  
30 with pro-inflammatory cytokines or exposure to environmental stress. JNK thus mediates the effect of extracellular stimuli on c-Jun. See Gupta, *supra*; and Minden,

*supra*. Accordingly, JNK is a physiological regulator of AP-1 transcriptional activity. Thus, inhibition of JNK activity will inhibit AP-1-dependent transcription of inflammatory and immune mediators which are implicated in pathological proliferative conditions, for example inflammatory diseases and neuro-degenerative diseases, in particular, rheumatoid arthritis. See, e.g. Swantek et al., Molecular and Cellular Biology, vol. 17 (1997) pp. 6274-6282; Maroney et al., J. Neuroscience, vol. 18 (1 Jan. 1998) pp. 104-111; and Minden, *supra*, at F92.

The rat homologue of JNK is also called SAPK (stress-activated protein kinase). SAPK isoforms share significant (>90%) sequence identity with the corresponding JNK isoforms [compare Kyriakis et al., Nature, Vol. 369 (12 May 1994) pp. 156-160 and Gupta et al., *supra*]. Both JNK and SAPK are capable of phosphorylation of the c-Jun substrate and thus have very similar enzyme activity. JNK and SAPK are part of a protein kinase cascade that is activated by various extracellular stimuli. See e.g. Minden *supra*; and Kyriakis et al., BioEssays Vol. 18 (1996) pp. 567-577. JNK and SAPK each can be activated by phosphorylation on specific threonine and tyrosine residues by dual specificity MAP kinase kinases such as MKK4, SEK-1, or MKK7. See Kyriakis et al., *supra*; and Tournier et al., Proceedings of the National Academy of Sciences USA Vol. 94 (July 1997), pp. 7337-7342). The dual specificity MAP kinase kinases can be activated by phosphorylation on serine and/or threonine residues by MAP kinase kinase kinases such as MEKK-1. Thus, measurement of JNK or SAPK enzyme activity may be enhanced by activation by the upstream or preceding kinases. Moreover, measurement of SAPK inhibition closely correlates with JNK inhibition.

Inhibitors of protein kinase catalytic activity are known in the art. See US Pat. No. 5,792,783 (3-heteroaryl-2-indolinones that modulate/inhibit tyrosine kinase signal transduction); WO 98/24432 (indoline compounds that inhibit *FLK* protein kinase); WO 97/45409 (substituted tetrahydropyrimidin-oxindole analogues that inhibit tyrosine kinase). In particular, small molecule inhibitors typically block the binding of substrates by tightly interacting with the protein kinase ATP binding site (or "active

site"). See WO 98/24432. It is desirable to identify small-molecule compounds that may be readily synthesized and are effective in inhibiting the catalytic activity of protein kinases, in particular of the JNK protein kinases.

5 Indolinone (also known as oxindole) compounds asserted to be useful in the regulating abnormal cell proliferation through tyrosine kinase inhibition are disclosed for example in WO 96/40116, WO 98/07695, WO 95/01349, WO 96/32380, WO 96/22976, WO 96/16964, WO 98/50356 (2-indolinone derivatives as modulators of protein kinase activity); Mohammadi et. al, Science, Vol. 276, 9 May 1997, pp. 955-  
10 960. Oxindole derivatives have also been described for various other therapeutic uses: 5,206,261 (improvement of cerebral function); WO 92/07830 (peptide antagonists); EP 580 502 A1 (antioxidants).

There continues to be a need for easily synthesized, small-molecule  
15 compounds effective in inhibiting JNK protein kinase and thus useful in the treatment or control of pathological proliferative conditions, for example inflammatory diseases and neuro-degenerative diseases, in particular, rheumatoid arthritis. It is thus an object of this invention to provide such compounds and compositions containing such  
20 compounds.

The present invention relates to 4-aryloxindoles capable of inhibiting the activity of one or more JNK protein kinases. Such compounds are useful for the treatment of inflammatory diseases and neuro-degenerative diseases. In particular, the compounds of the present invention are especially useful in the treatment or  
25 control of rheumatoid arthritis.

#### Examples

25           The compounds of the present invention may be synthesized according to known techniques, such as for example General Scheme I provided above. The following examples illustrate preferred methods for synthesizing the compounds and formulations of the present invention.

**Example 1: General Synthesis Methods and Starting Materials****Method F: Preparation of carboxylic acids from the methyl esters**

- 5 The appropriate methyl ester (0.14 mmol) was dissolved in a mixture of 2 mL tetrahydrofuran and 2 mL water. Lithium hydroxide (2.8 mmol, 20 equiv.) was added, and the reaction was stirred at room temperature for 14 hours. The tetrahydrofuran was then evaporated and 10 mL water was added. The aqueous layer was then extracted with ethyl acetate (2x10 mL). These ethyl acetate extracts were discarded.
- 10 The aqueous layer was then acidified to pH = 2 with 1 N hydrochloric acid, and extracted with ethyl acetate (4x20 mL). The combined organic extracts were washed with a saturated solution of sodium chloride and were then dried over magnesium sulfate. The ethyl acetate was then evaporated and the product was recrystallized from ethanol.

15

**Method L:**

- To a solution of nitro compound in 10% water in methanol was added Zn dust and NH<sub>4</sub>Cl. The mixture was heated at reflux for 6 h then filtered through Celite<sup>®</sup>
- 20 (Fisher Scientific). Filtrate was concentrated *in vacuo*. The product was purified via either flash column chromatography (SiO<sub>2</sub>, 230-400 mesh with ethyl acetate/hexanes as solvent) or with reverse phase HPLC (using either acetonitrile / water or acetonitrile / water / trifluoroacetic acid as solvent).

**Method M:**

To a mixture of amino compound in THF and saturated aqueous  $\text{NaHCO}_3$  was added a THF solution of the acid chloride dropwise. The mixture was stirred for from 3 h to 10 days at room temperature then diluted with ethyl acetate. The phases were separated and the organic solution was washed with water then dried ( $\text{MgSO}_4$ ). The product was purified via either flash column chromatography ( $\text{SiO}_2$ , 230-400 mesh with ethyl acetate/hexanes as solvent) or with reverse phase HPLC (using either acetonitrile / water or acetonitrile / water / trifluoroacetic acid as solvent).

**Method N: Preparation of 3-arylmethylene-substituted oxindoles via coupling with aldehyde**

A solution or suspension of the appropriate oxindole (1 mmol), and excess aldehyde (1 to 2 mmol) in 2 mL of 1% piperidine in 2-propanol was heated at between 60 to 90 °C for 1 to 24 hours. Hot water (2 mL) was added. On cooling, the crystallized product was filtered off, washed with aqueous 2-propanol and dried.

**Method S: Preparation of 4-aryloxindoles or 4-heteroaryloxindoles via Palladium(0)-mediated coupling**

To a solution of the appropriate 4-iodooxindole (see T. Fukuyama et. al., *J. Am. Chem. Soc.* 118:7426-7427 (1996)) or 4-bromooxindole (see T. Kosuge et. al., *Chem. Pharm. Bull.* 33(4):1414-1418 (1985)) in dimethoxyethane was added an aryl or heteroaryl boronic acid, palladium catalyst, and an aqueous solution of 2M  $\text{Na}_2\text{CO}_3$ . The mixture was heated at reflux for up to 4 days. After cooling, the reaction mixture was filtered and concentrated. The product was purified via either

flash column chromatography (SiO<sub>2</sub>, 230-400 mesh with ethyl acetate/hexanes as solvent) or with reverse phase HPLC (using either acetonitrile / water or acetonitrile / water / trifluoroacetic acid as solvent).

**Example 66: SAPK Inhibitory Activity**

The SAPK inhibitory activity of the compounds of the invention is demonstrated below. These effects indicate that the compounds of the present invention are useful in treating inflammatory diseases such as, for example, rheumatoid arthritis.

**SAPK FlashPlate Assay**

Human JNK is highly homologous to rat SAPK. To measure the inhibitory activity of test compounds, the compounds were tested in the rat SAPK assay.

For the SAPK assay, purified GST-c-Jun (a chimeric protein containing c-Jun, a natural substrate of JNK) was coated on 96 well FlashPlates (New England Nuclear, Boston, MA). Purified rat SAPK (isoform b, Kyriakis et al. *supra*) was preincubated with preparations containing MEKK-1 and MKK4 for 30 minutes at 37°C in assay buffer containing 25 mM HEPES, pH 7.5, 150 mM NaCl, 20 mM MgCl<sub>2</sub>, 2 mM DTT, 0.001% Tween 20, 1 mM ATP freshly added. In the preincubation step, MEKK-1 phosphorylates and activates MKK-4, which in turn phosphorylates and activates SAPK. The activated SAPK was then added to the c-Jun coated FlashPlates along with <sup>33</sup>P-ATP (0.32 mCi per reaction) and test compounds. The plates were incubated for 30 minutes at 37°C, then washed with PBS, 0.01% Tween 20, and counted in the Topcount scintillation counter (Packard Instrument Co., Downers Grove, IL). Dilutions of compounds were tested in duplicate in each assay. The percent inhibition of c-Jun phosphorylation (a measure of inhibition of SAPK activity) was determined by the following formula:

$$100 \times \left[ 1 - \frac{\text{test compound} - \text{nonspecific}}{\text{total} - \text{nonspecific}} \right]$$

where "test compound" refers to the average counts per minute of the test duplicates, "nonspecific" refers to the average counts per minute when no SAPK was added, and "total" refers to the average counts per minute when no compound was added.

The results of the SAPK assay with various test compounds is summarized below in Table I.

### 5 **U937 Cell-Based Assay**

The U937 cells, a human monocyte/macrophage cell line, was obtained from the ATTC and grown in the recommended medium. These cells when stimulated with lipopolysaccharide (LPS) release TNF, another inflammatory mediator implicated in the JNK pathway (Swantek et al., *supra*) and IL-6. In this assay the ability of a test  
10 compound to block TNF expression is evaluated.

The U937 cells were suspension cells which when stimulated with phorbol myristate acetate (PMA) (Sigma, St. Louis, MO) became adherent. After PMA  
15 stimulation the cells were washed in cell culture medium and plated at  $1 \times 10^5$  cells/well in 96 well plates. The following day the test compounds and dexamethasone control (Sigma, St. Louis, MO) were added to the cells for 1 hour of preincubation. Then the cells were stimulated with LPS (Sigma, St. Louis, MO). After

an additional 24 hours of incubation the supernatants were removed and assayed for TNF- $\alpha$  and IL-6 by ELISA. The IL-6 ELISA was run as described previously for the MG63 assay. The TNF ELISA was run using a kit supplied by Genzyme (Cambridge, MA).

5

In the ELISA, 96 well plates were coated with antibody to TNF- $\alpha$  or IL-6. Supernatants were added to the coated plates and any antigen (TNF- $\alpha$  or IL-6) in the supernatant bound to the antibody coated on the plates. The plates were then washed with PBS containing 0.05% Tween 20 (Sigma, St. Louis, MO) and the  
10 biotinylated secondary antibody was added. This secondary antibody binds to the already bound antigen creating a "sandwich effect". Plates were washed as described above and horseradish peroxidase (HRP)-streptavidin conjugate (Sigma, St. Louis, MO) was added to the plates. HRP-streptavidin bound to the biotin-antibody conjugate. The plates were washed and TMB substrate (Kirkegaard and Perry Labs,  
15 Gaithersburg, MD) was added to the wells. This substrate changes color in the presence of HRP-streptavidin. The intensity of the color (measured at 450 nm) is proportional to the amount of TNF- $\alpha$  or IL-6 produced by the U937 cells upon exposure to LPS and the test compounds. Optical density values were converted to concentration (pg/ml or Units/ml) based on a standard curve included in the assay.  
20 IC<sub>50</sub> values for each test compound were determined from the linear regression of a plot of the logarithm of the concentration of compound versus amount of TNF- $\alpha$  or IL-6 secreted. (The TNF- $\alpha$  antibodies and the IL-6 antibodies were obtained from either Genzyme, Cambridge, MA or Pharmingen, San Diego, CA.).

25 The results of this assay on various test compounds is summarized below in Table II.
